

Every java class must have at-least one constructor [We cannot think about a java class without constructor] either implicitly added by java compiler OR explicitly written by developer.

Why compiler automatically provides no argument default constructor to our class :

Diagram

Work of new keyword :

* It is used to allocate the memory for non static members (non static field + non static methods), while allocating the memory for non static fields, It takes the help of Java compiler for type information, It will initialize all the non static fields with default value according to the data type.

Data Type	Default Value (for fields)
byte	0
short	0
int	0
long	0L
float	0.0f
double	0.0d
char	'�����'
String (or any object)	null
boolean	false

The process of allocating the memory for non static members is known as "Instantiation Process"

Without default constructor, Object creation is not possible in java by using new keyword, if the class does not contain user-defined constructor means developer responsibility.

As we know only class level variables are having default values so, new keyword is responsible to provide default value for the non-static fields with the help of Java compiler.
